ABSTRACT

Two model field theories involving scalar and fermion fields with contact interactions are analyzed. The models are solved in the large- N limit. It is shown that chiral symmetry of the Lagrangian is realized in the spectrum. The anomalous magnetic moment of the composite fermions is shown to be m_F/m_B^2 , where m_F and m_B are the masses of the fermionic and bosonic preons, respectively. Finally a semi-realistic model which incorporates the known gauge interactions is constructed.

I. INTRODUCTION

It is widely accepted that the main problem in constructing composite models for quarks and leptons consists in obtaining composite fermions whose mass is much smaller than the scale of binding. In the dynamical mechanisms proposed so far such fermions arise as massless "baryons" in a Yang-Mills theory with unbroken or partially broken chiral symmetry [1], as Goldstone fermions of dynamically broken supersymmetry [2], or as supersymmetric partners of Goldstone bosons of a spontaneously broken global symmetry [3]. Although all these approaches have contributed to the development of new ideas, they have not produced a simple calculable model in which one could compute things like masses of the bound states, their anomalous magnetic moments etc.

In this paper we examine two model field theories involving scalar and fermion fields with contact interactions. These interactions are non-renormalizable, therefore we have to keep the cutoff as a physical parameter. We consider N -component scalar and fermion fields in the limit of large N and solve the theory to the leading order in $1/N$.

We find that in this limit the chiral symmetry of the Lagrangian is generally realized in the spectrum. The mass of the fermion-scalar bound state is proportional to the explicit chiral symmetry breaking terms as, for example, the

mass term for the fermionic field. In particular, the mass of the bound state fermion does not depend on the mass of the scalar field.

We compute the electromagnetic couplings of the composite fermions with the particular interest focused on their anomalous magnetic moments. They turn out to be of order m_F/m_B^2 , where m_F and m_B are the masses of the fermionic and bosonic constituents, respectively, thus confirming suggestions made earlier by several authors.

Finally, we show how to incorporate the gauge interactions in our model and construct a semi-realistic model for quarks and leptons.

II. THE FIRST MODEL

In this Section we discuss our simplest model described by the Lagrangian

$$\mathcal{L}_1 = \bar{\psi}(i\not{\partial} - m)\psi + \phi^\dagger(-\square - \mu^2)\phi - \frac{g}{N} \phi \cdot \bar{\psi} \psi \cdot \phi^\dagger \quad (2.1)$$

where $\phi \equiv (\phi_1, \phi_2, \dots, \phi_N)$ and $\psi \equiv (\psi_1, \psi_2, \dots, \psi_N)$ are N-component scalar and fermion fields respectively. Note that the chiral symmetry is explicitly broken by the interaction and by the fermion mass term (if $m \neq 0$). The latter is included for the sake of generality and the zero fermion mass limit of the theory is straightforward. The Lagrangian (2.1) is the simplest one describing interacting

scalar and fermion fields. Since this theory is not renormalizable (g has dimension $(\text{mass})^{-1}$) we shall introduce an ultraviolet cutoff Λ for the momentum integrations. Then our model is an analog of the Nambu-Jona-Lasinio model [4] with fermionic bound states.

We now proceed to solve the theory in the leading order in $1/N$ in the large N limit. The dominant graphs in this limit will be those containing the maximal number of scalar-fermion loops, Fig. 1. In order to sum up these diagrams, we transform the Lagrangian (2.1) to an equivalent Lagrangian of the gaussian form with respect to ψ and ϕ by adding the following term to it:

$$-\frac{N}{g} \left(\bar{q} + \frac{g}{N} \bar{\psi} \cdot \phi \gamma_5 \right) \left(q - \frac{g}{N} \gamma_5 \phi^\dagger \cdot \psi \right). \quad (2.2)$$

The contribution of this term reduces to just a numerical constant in the path integral formalism. The resulting equivalent Lagrangian is given by

$$\mathcal{L} = \bar{\psi}(i\not{\partial} - m)\psi + \phi^\dagger(-\square - \mu^2)\phi - \frac{N}{g} \bar{q}q + \left(\bar{q} \gamma_5 \psi \cdot \phi^\dagger - \bar{\psi} \cdot \phi \gamma_5 q \right) \quad (2.3)$$

If we eliminate \bar{q} and q from this Lagrangian by using their equations of motion, we will recover the original Lagrangian, Eq. (2.1). As is seen from Eq. (2.2), q represents a composite operator $\gamma_5 \phi^\dagger \cdot \psi$, so that it describes a composite fermion if its propagator has a pole.

In order to find the mass of the bound state, we integrate out ψ and ϕ fields in favor of q and \bar{q} and define the effective action for q and \bar{q} by

$$\exp\{i S_{\text{eff}}(q, \bar{q})\} \equiv \int [d\phi_i d\phi_i^\dagger d\psi_i d\bar{\psi}_i] \exp\{i \int \mathcal{L}(x) d^4x\}. \quad (2.4)$$

After the integrations over ψ and ϕ are performed, we find

$$\begin{aligned} S_{\text{eff}} &= -\frac{N}{g} \int dx \bar{q} q + i N \text{Tr} \ln \left(1 - \frac{1}{\square + \mu^2} \bar{q} \gamma_5 \frac{1}{i \not{D} - m} \gamma_5 q \right) \\ &= S_0 + S_{\text{int}}, \end{aligned} \quad (2.5)$$

where S_0 denotes the bilinear term for q and S_{int} the rest:

$$S_0 = -\frac{N}{g} \int dx \bar{q} q - i N \text{Tr} \left(\frac{1}{\square + \mu^2} \bar{q} \gamma_5 \frac{1}{i \not{D} - m} \gamma_5 q \right), \quad (2.6)$$

and

$$S_{\text{int}} = -i N \sum_{n=2}^{\infty} \frac{1}{n} \text{Tr} \left(\frac{1}{\square + \mu^2} \bar{q} \gamma_5 \frac{1}{i \not{D} - m} \gamma_5 q \right)^n. \quad (2.7)$$

If we wish to include gauge fields, we have to replace \square and \not{D} with the appropriate covariant derivatives in Eqs. (2.6) and (2.7).

It is now easy to obtain the propagator of the field q defined by

$$S_0 = \int d^4x d^4y \bar{q}(x) i G^{-1}(x, y) q(y), \quad (2.8)$$

namely,

$$i G^{-1}(p) = -\frac{N}{g} + N \int \frac{d^4 k}{(2\pi)^4} i \frac{1}{\mu^2 - (p-k)^2} \gamma_5 \frac{1}{\not{k} - m} \gamma_5$$

$$\equiv \not{p} A(p^2) - B(p^2), \quad (2.9)$$

where

$$A(p^2) = \frac{N}{(4\pi)^2} \frac{1}{2} \ln \frac{\Lambda^2}{\mu^2} \equiv Z^{-1} \quad (2.10)$$

and

$$B(p^2) = \frac{N}{g} + \frac{Nm}{(4\pi)^2} \ln \frac{\Lambda^2}{\mu^2} \quad (2.11)$$

for $m \ll \mu \ll \Lambda$.

In order to obtain the correct normalization, we introduce the renormalized composite quark field and the renormalized coupling by

$$q_R \equiv Z^{-1/2} q \quad (2.12)$$

and

$$g_R \equiv Z^{-1} g. \quad (2.13)$$

Then the renormalized composite quark propagator is given by

$$i G_R^{-1} = Z i G^{-1} = \not{p} - M,$$

where

$$M = \frac{B(p^2)}{A} = 2m + \frac{1}{g_R}.$$

As long as $m \ll \mu \ll \Lambda$, the mass of the composite quark is very

nearly independent of the mass of the scalar preon and can be made arbitrarily small by having a light fermionic preon and the large cutoff Λ (since $g_R \propto \ln \Lambda^2 / \mu^2$). At first glance this seems surprising--we obtain a light composite fermion by binding a light fermion and an arbitrarily heavy scalar. However this result can be understood in terms of the chiral symmetry of the Lagrangian (2.1). Eq. (2.15) gives the composite fermion mass as the sum of the chiral-symmetry-breaking terms. It is important that the chiral symmetry is realized in the Wigner mode.

III. ELECTROMAGNETIC INTERACTIONS AND THE ANOMALOUS MAGNETIC MOMENT

Phenomenologically the electromagnetic interactions and, in particular, the anomalous magnetic moments are very important tests of compositeness of quarks and leptons [5]. We investigate here the electromagnetic properties of the composite fermions described in previous Section.

Let e_F and e_S be the charges of the ψ and ϕ^+ fields, respectively. The electromagnetic interactions are then included by replacing the derivatives by the covariant derivatives,

$$\begin{aligned} \not{D} &\longrightarrow \not{D} - ie_F \not{A} \equiv \not{D}' \\ \square &\longrightarrow (\partial_\mu + ie_S A_\mu)^2 \equiv D^2 \end{aligned}$$

in the quadratic term of the action, Eq. (2.6), yielding

$$S^{(2)}(q, A_\mu) = -iN \text{Tr} \left(\frac{1}{D^2 + \mu^2} \bar{q} \gamma_5 \frac{1}{i\not{D} - m} \gamma_5 q \right) - \frac{N}{g} \int \bar{q} q d^4x. \quad (3.1)$$

We expand the propagators

$$\frac{1}{D^2 + \mu^2} = \frac{1}{\square + \mu^2} + \frac{1}{\square + \mu^2} (D^2 - \square^2) \frac{1}{\square + \mu^2} + \dots,$$

and

$$\frac{1}{i\not{D} - m} = \frac{1}{i\not{D} - m} + \frac{1}{i\not{D} - m} (i\not{D} - i\not{D}) \frac{1}{i\not{D} - m} + \dots,$$

and keep only the linear terms in A_μ ,

$$S^{(2)}(q, A_\mu) = S^{(2)}(q) + \Delta S^{(2)}(q), \quad (3.2)$$

where

$$\Delta S^{(2)}(q) \equiv N \int \frac{d^4k}{(2\pi)^4} \int \frac{d^4p}{(2\pi)^4} \bar{q}_R(-p-k) \Gamma^\mu(p, k) q_R(p) A_\mu(k). \quad (3.3)$$

The vertex function Γ^μ , diagrammatically represented in Fig. 2, is

$$\begin{aligned} Z \Gamma^\mu(p, k) = & i e_s \int \frac{d^4p'}{(2\pi)^4} \frac{1}{(p'+k)^2 - \mu^2} \frac{(2p'+k)^\mu}{\mu^2 - p'^2} \gamma_5 \frac{1}{\not{p}' - \not{p}' - m} \gamma_5 \\ & + i e_f \int \frac{d^4p}{(2\pi)^4} \frac{1}{(p-p')^2 - \mu^2} \gamma_5 \frac{1}{\not{p}' + \not{k} - m} \gamma^\mu \frac{1}{\not{p}' - m} \gamma_5. \end{aligned} \quad (3.4)$$

In order to obtain the local effective Lagrangian, we expand $\Gamma^\mu(p, k)$ in powers of k^μ ,

$$\Gamma^\mu(p, k) = \Gamma_0^\mu(p) + k_\nu \Gamma^{\mu\nu}(p) + \dots \quad (3.5)$$

Γ_0^μ and $\Gamma^{\mu\nu}$ are readily computed by expanding the propagators,

$$\frac{1}{(p'+k)^2 - \mu^2} = \frac{1}{p'^2 - \mu^2} - \frac{1}{p'^2 - \mu^2} 2p' \cdot k \frac{1}{p'^2 - \mu^2} + \dots$$

and

$$\frac{1}{\not{p}' + \not{k} - m} = \frac{1}{\not{p}' - m} - \frac{1}{\not{p}' - m} \not{k} \frac{1}{\not{p}' - m} + \dots$$

For $Z\Gamma_0^\mu$ we obtain

$$\begin{aligned} Z\Gamma_0^\mu(p) &= -ie_s \int \frac{d^4 p'}{(2\pi)^4} \frac{2p'^\mu}{(p'^2 - \mu^2)^2} \gamma_5 \frac{1}{\not{p} - \not{p}' - m} \gamma_5 \\ &\quad + ie_F \int \frac{d^4 p'}{(2\pi)^4} \frac{1}{(p-p')^2 - \mu^2} \gamma_5 \frac{1}{\not{p}' - m} \gamma^\mu \frac{1}{\not{p}' - m} \gamma_5 \\ &= (e_s + e_F) \gamma^\mu \frac{1}{2(4\pi)^2} \ln \frac{\Lambda^2}{\mu^2}, \end{aligned} \quad (3.6)$$

and for the renormalized vertex function

$$\Gamma_0^\mu(p) = (e_s + e_F) \gamma^\mu \equiv e \gamma^\mu. \quad (3.7)$$

As expected, the bound state couples to the photon as a fermion, with the strength determined by the total charge.

Our main goal in this Section is to calculate the anomalous magnetic moment of the bound state, which is obtained as the antisymmetric part of $Z\Gamma^{\mu\nu}(p)$:

$$Z(\Gamma^{\mu\nu} - \Gamma^{\nu\mu}) = \frac{2ie}{(4\pi)^2} m \sigma^{\mu\nu} \frac{1}{\mu^2} \ln \frac{\mu^2}{m^2}. \quad (3.8)$$

The effective Lagrangian is

$$\mathcal{L}_{\text{eff}} = N \frac{em}{\mu^2} \frac{\ln \frac{\mu^2}{m^2}}{\ln \frac{\Lambda^2}{\mu^2}} \bar{q}_R \sigma^{\mu\nu} q_R F_{\mu\nu}, \quad (3.9)$$

where $q_R \equiv Z^{-1/2} q$, with $q = g/N \gamma_5 \phi^\dagger \cdot \psi$, is the renormalized composite fermion field. The anomalous magnetic moment is proportional to the mass of the fermionic constituent and inversely proportional to the scalar mass squared. Although this was suggested by several people [6], we find it reassuring that in our model that can actually be confirmed by explicit calculation.

One might attempt to construct a realistic composite model for quarks and leptons based on the model proposed here. However there appears to be no simple way of incorporating the gauge theory of weak interactions. The problem is that the interaction term in the Lagrangian (2.1), not being chirally invariant, breaks $SU(2)$ gauge symmetry.

IV. THE SECOND MODEL

The difficulties in incorporating the weak interactions in the model described in the preceding sections are related to the fact that the interaction is not chirally invariant. For that reason we study here a similar model, but with a contact interaction which is chirally invariant. The Lagrangian of the model is

$$\mathcal{L}_2 = \bar{\psi}(i\not{\partial} - m)\psi + \phi^\dagger(-\square - \mu^2)\phi - \frac{g}{N}(\bar{\psi} \cdot \phi) i \not{\partial} (\psi \cdot \phi^\dagger), \quad (4.1)$$

where the notation is the same as in previous section, except that the coupling constant g now has dimension $(\text{mass})^{-2}$. Chiral symmetry is now broken only by the possible fermion mass term, and if it is not spontaneously broken we might expect the mass of the composite fermion to be proportional to m .

In order to solve the theory (4.1) in the large N limit we add the following term to \mathcal{L}_2

$$\frac{N}{g} \left(\bar{q} - \frac{g}{N} \phi \cdot \bar{\psi} \gamma_5 i \not{\partial} \right) (i \not{\partial})^{-1} \left(q + \frac{g}{N} i \not{\partial} \gamma_5 \psi \cdot \phi^\dagger \right) \quad (4.2)$$

leading to the following equivalent Lagrangian:

$$\mathcal{L} = \bar{\psi}(i\not{\partial} - m)\psi + \phi^\dagger(-\square - \mu^2)\phi + (\bar{q} \gamma_5 \psi \cdot \phi^\dagger - \bar{\psi} \cdot \phi \gamma_5 q) + \frac{N}{g} \bar{q} (i \not{\partial})^{-1} q. \quad (4.3)$$

This Lagrangian, except for the mass term for ψ , is invariant under chiral rotation,

$$\begin{aligned}
\psi &\rightarrow e^{i\gamma_5 \theta} \psi, \\
q &\rightarrow e^{-i\gamma_5 \theta} q, \\
\phi &\rightarrow \phi.
\end{aligned}
\tag{4.4}$$

The calculations are done analogously to those in the previous section and the result for the propagator of the composite field q can again be written as

$$i G^{-1}(p) = \not{p} A(p^2) - B(p^2),$$

where now

$$A(p^2) = \frac{N}{2(4\pi)^2} \ln \frac{\Lambda^2}{\mu^2} + \frac{N}{g} \frac{1}{p^2}, \tag{4.5}$$

and

$$B(p^2) = \frac{Nm}{(4\pi)^2} \ln \frac{\Lambda^2}{\mu^2}. \tag{4.6}$$

When $\Lambda^2 \gg \mu^2, m^2, p^2$, the bound state propagator becomes

$$i G^{-1}(p) = Z^{-1}(\not{p} - 2m). \tag{4.7}$$

Thus the mass of the bound state is twice the mass of the fermionic preon and independent of the mass of the scalar preon. Chiral symmetry of the Lagrangian is again realized in the spectrum and in presence of explicit breaking (i.e. $m \neq 0$) the bound state acquires mass directly proportional to the magnitude of the symmetry breaking term.

V. A MODEL OF QUARKS AND LEPTONS

Since our model is a non-confining one, the preon ψ has to be an observed particle as well as the composite fermion q . It is tempting to identify ψ and q with leptons and quarks. In this section we present a semi-realistic model based on this idea. In order to incorporate the strong, weak and electromagnetic interactions we have to use the chiral symmetric Lagrangian (4.1), since the simplest Lagrangian (2.1) breaks gauge invariance. For simplicity we discuss the model of one generation of leptons and quarks.

We assume the standard assignment for leptons, namely

$$\psi_L = \begin{pmatrix} \nu \\ e \end{pmatrix}_L, \quad I=1/2, \quad Y=-1$$

$$\psi_R = \nu_R \text{ and } e_R, \quad I=0, Y=0 \text{ and } I=0, Y=-2.$$

The right handed neutrino, of course, does not couple to the gauge bosons. The scalars appear in a color triplet ϕ , with $I=0$ and $Y=-2/3$ and a color singlet $H = \begin{pmatrix} H^+ \\ H^0 \end{pmatrix}$ with $I=1/2$ and $Y=1$.

Our model Lagrangian for these fields is

$$\begin{aligned} \mathcal{L} = & \bar{\psi}_L i \not{D} \psi_L + \bar{\nu}_R i \not{D} \nu_R + \bar{e}_R i \not{D} e_R + \phi^\dagger (-D^2 - \mu^2) \phi \\ & - f(\bar{\psi}_L H e_R + \text{h.c.}) \\ & - \frac{g}{N} \{ (\bar{\psi}_L \phi) i \not{D} (\psi_L \phi^\dagger) + (\bar{e}_R \phi) i \not{D} (e_R \phi^\dagger) + (\bar{\nu}_R \phi) i \not{D} (\nu_R \phi^\dagger) \}, \quad (5.1) \end{aligned}$$

where

$$D_\mu \psi = \left(\partial_\mu - ig I_\alpha W_\mu^\alpha - ig' \frac{1}{2} \gamma B_\mu \right) \psi,$$

with $I_\alpha = 1/2 \tau_\alpha$ for $I=1/2$ and zero for $I=0$, and

$$D_\mu \phi = \left(\partial_\mu - ig_s \frac{1}{2} \lambda_\alpha A_\mu^\alpha - ig' \frac{1}{2} \gamma B_\mu \right) \phi.$$

A_μ^α , W_μ^α and B_μ are the gauge fields of $SU(3)_C$, $SU(2)_L$ and $U(1)$ interactions.

As in the previous sections we add the following terms to the Lagrangian:

$$\begin{aligned} & \frac{N}{g} \left(\bar{q}_R^c - \frac{g}{N} \phi \bar{\psi}_L i \not{D} \right) (i \not{D})^{-1} \left(q_R^c - \frac{g}{N} i \not{D} \psi_L \phi^\dagger \right) \\ & + \frac{N}{g} \left(\bar{u}_L^c + \frac{g}{N} \phi \bar{e}_R i \not{D} \right) (i \not{D})^{-1} \left(u_L^c + \frac{g}{N} i \not{D} e_R \phi^\dagger \right) \\ & + \frac{N}{g} \left(\bar{d}_L^c + \frac{g}{N} \phi \bar{\nu}_R i \not{D} \right) (i \not{D})^{-1} \left(d_L^c + \frac{g}{N} i \not{D} \nu_R \phi^\dagger \right), \end{aligned}$$

where the superscript c indicates the charge conjugate fields, and

$$q_R^c \equiv \sigma_2 \begin{pmatrix} u_R^c \\ d_R^c \end{pmatrix} = i \begin{pmatrix} -d_R^c \\ u_R^c \end{pmatrix}.$$

With that we obtain the linearized Lagrangian

$$\begin{aligned}
\mathcal{L} = & \bar{\psi}_L i \not{D} \psi_L + \bar{\nu}_R i \not{D} \nu_R + \bar{e}_R i \not{D} e_R + \phi^\dagger (-D^2 - \mu^2) \phi \\
& - f (\bar{\psi}_L H e_R + \text{h.c.}) \\
& + \frac{N}{g} \{ \bar{q}_R^c (i \not{D})^{-1} q_R^c + \bar{u}_L^c (i \not{D})^{-1} u_L^c + \bar{d}_L^c (i \not{D})^{-1} d_L^c \} \\
& - (\bar{q}_R^c \psi_L \phi^\dagger + \phi \bar{\psi}_L q_R^c - \bar{u}_L^c e_R \phi^\dagger - \phi \bar{e}_R u_L^c - d_L^c \nu_R \phi^\dagger - \phi \bar{\nu}_R d_L^c).
\end{aligned} \tag{5.2}$$

Variations with respect to q_R^c , u_L^c and d_L^c give

$$\begin{aligned}
q_R^c &= \frac{g}{N} i \not{D} (\psi_L \phi^\dagger), \\
u_L^c &= -\frac{g}{N} i \not{D} (e_R \phi^\dagger), \\
d_L^c &= -\frac{g}{N} i \not{D} (\nu_R \phi^\dagger).
\end{aligned} \tag{5.3}$$

The reason why we have to use the charge conjugate fields is that, e.g., $\not{D}(\psi_L \phi^\dagger)$ is a right handed field with the weak isospin 1/2, and cannot be assigned to either q_L or q_R . Hence it is assigned to q_R^c which has the same quantum numbers.

By eliminating the ϕ field we obtain the Lagrangian of the standard model for quarks and leptons as an effective Lagrangian of our composite model, Eq. (5.1). In the framework of our model this essentially completes the program which the realistic model for composite quarks and leptons will eventually have to fulfill: starting from the fundamental Lagrangian, obtain the mass spectrum of the composite fermions and derive the standard model as an effective low-energy theory.

The main purpose of this paper was to present a sufficiently simple model in which this program can be carried through explicitly. From the point of view of phenomenology, the main criticism of the model described here is that it does not appear to offer a clue as to the generation problem. One could, of course, have preons appearing in generations, but to our mind that goes against the main philosophy of having composite quarks and leptons. The contact interaction, Eq. (4.1), is certainly too simple to produce the generation structure dynamically.

FIGURE CAPTIONS

Fig. 1: The dominant contribution to the scalar-fermion bound state in the large N limit.

Fig. 2: The electromagnetic vertex of the composite fermion.

Fig. 1

$$\frac{\xi^k}{p} = \text{tadpole diagram} + \text{bubble diagram}$$

The equation shows the sum of two diagrams. The first diagram on the left is a tadpole diagram: a horizontal solid line labeled p at both ends, with a wavy line labeled ξ^k attached to the center. This is followed by an equals sign. To the right of the equals sign is the sum of two diagrams. The first is a bubble diagram: a horizontal solid line labeled p at both ends, with a dashed line forming a loop above it, and a wavy line labeled ξ^k attached to the top of the loop. The second diagram is another bubble diagram: a horizontal solid line labeled p at both ends, with a dashed line forming a loop above it, and a wavy line labeled ξ^k attached to the top of the loop.
